What happens to your body when you run a marathon?

From your heart to your muscles to your brain and your digestive system, here's what to know

Heart

As physical exertion increases, so too does the heart rate. The heart starts to pump more blood to deliver more oxygen to the body's systems, especially the large muscles propelling the runner.

"It really comes down to blood flow and the body's ability to put blood where it needs it most," said Emilio Ortiz Pinilla, professor in the division of exercise physiology at WVU School of Medicine. "Major muscles need the most blood, and the heart is responding to that."

A seasoned runner will have a smaller change from their resting heart rate to their heart rate during a race. Training will also help adapted over the course of training, he said.

Trained-with fluid loss from sweating, the impact of an overactive heart can lead to risk of dehydration and organ damage.

"When you're doing prolonged activity, you gotta make sure you're hydrating," said Brian Lairmore, associate professor and program director of exercise science at Seton Hill University. "When you sweat, you're losing electrolytes and fluid, which thickens the blood. This makes it harder for the heart to pump, because breathing gets heavier. It's all one big connected machine."

Muscles

The musculoskeletal system certainly takes a toll during a marathon, absorbing the vibrations and stress of the body's exertion.

Runners take about 30,000 steps in a marathon, said Frank Velasquez, director of sports performance at Allegheny Health Network, absorbing three to four times their body weight with each strike. This means strength training will be of great import to runners.

"The strength of your muscles is going to help lessen the impact on your joints," he said.

During a marathon, blood pumped by the heart floods to large muscle groups, helping to energize those muscles. But as with the heart, the body can experience microscopic tears in muscles. These muscles will start to repair themselves and ultimately be better than they were before, said Jeff Fleming, primary care sports medicine physician at UPMC and an assistant professor at the University of Pittsburgh's orthopaedic surgery department.

Training is crucial to prevent muscle and ligament strains and larger tears. The body will adapt to heavier exertion as a runner scales up endurance, but going too hard too quickly can lead to injury.

After a big exertion, a runner can also develop what's called delayed-onset muscle soreness, explained Lairmore. Usually, this peaks around a couple days but, after a marathon, it can last up to seven days.

This happens because during a run as long as a marathon, the muscle fibers break down, and lactic acid and inflammatory chemicals are flooding the body, signaling damage. A buildup of lactic acid is generally perceived as muscle soreness.

Brain

Runners often speak of the "runner's high," when the brain evolves a deluge of exercise-induced endorphins. These hormones can relieve pain and stress and boost mood.

But recent studies have suggested that endorphins are too large to cross the blood-brain barrier, and that it may actually be cannabinoids bodies naturally produce that are responsible for the runner's high.

These chemicals, called endocannabinoids, activate receptors throughout the brain and body and relieve anxiety, depression and pain, and can lead to feelings of euphoria. One study in mice found that a state of aerobic exercise increased both endocannabinoids and brain-derived neurotrophic factor, or BDNF, after-which "brain fertilizer" for the generation of cells to help the brain work properly.

Races are always going to have some element of mental stress and challenge, said Velasquez, which may be enhanced by uncertainties in the weather. (Pittsburgh can see unpredictable rain this time of year.)

"There's a lot of alone time during a race like this, even if you think you're going to run with a partner," he said. "I've done different races where I dedicate each mile to a family member. That helped get me through it."

Digestive system, kidneys

With blood flowing toward the leg muscles and the lungs, less blood is prioritized for other bodily systems, including the digestive system and the kidneys. This may lead to feeling nauseated or cramping, or vomiting during the race.

"To me, that's a warning sign that you're going too hard," said Larmore.

The risk for diarrhea often increases during marathons, in part from the continued jostling of the digestive system, dehydration and reduced blood flow.

Eating a big meal right after a long race may also lead to uncomfortable symptoms.

"Your digestive tract is kind of in shock," said Velasquez. "All your energy has been expended for muscle function. The last thing you want to do is get out and have a big spaghetti dinner or get intoxicated."

Velasquez has run four marathons and said he enjoys grabbing a beer after the race, but will take it easy for the rest of the day, making sure to rehydrate with fluids and electrolytes and eating light food, like a banana, until later in the day.

One 2019 study conducted by Yale researchers found that 84% of runners whose blood they sampled tested positive for acute kidney injury. This was associated with overall heat, but also with an imbalance in nutrients like sodium and causing stress on the kidney.

This condition is rare and reversible, but it highlights the importance of hydrating properly before, during and after the race to prevent further injury.

Immune system

Studies show that the immune system is temporarily compromised for about a week after a big race, those interviewed for this story said. It has just used up all its stores to help a runner cross the finish line and will be depleted.

"A marathon in itself is a pretty big insult to the body," said Pietilli. "People training for one are generally pretty fit, have a better immune system and lower risk of cardiovascular disease, but this one act of prolonged activity is really going to affect most runners in a negative way."

Pathogen-killing immune cells are reduced, said Pietilli, as is the antibody IGA, which typically lines the nasal cavities, leaving a runner at a higher propensity for an upper respiratory infection.

There's even a term for it: "marathon flu," Getting proper sleep, meals and hydration the week before and after a big race can help reduce this risk.

The importance of training

"Running a marathon, overall, is not for the faint of heart," said Larmore. "I have conversations with individuals all the time, where I tell them, 'You gotta train ahead of time.' You can't just wake up and run a marathon."

Velasquez specifically recommended strength training to improve the body's ability to absorb shock and weight impact, protect the joints and prevent too much muscle wear and tear. Ideally, this would be three times a week, with two days a week of strength training.

It's generally good to practice being in discomfort, but it's also important to listen to the body.

The body "gets stronger after doing hard things," said Fleming. "Just be mindful that you can overdo it and cross a line. As you train, you get better at figuring out where that line is."

And if 26.2 miles doesn't sound like a fun challenge — that's OK, too.

"Running is a good activity, but it's not for everybody," said Velasquez. "That's why we have activities like hiking, swimming and walking the dog. ... I have plenty of people who are in great shape and have never run a race in their lives."
